SENSITIVE AND CONFIDENTIAL

fyi

p and s

Looks like around Feb 26-28 a go for Stanford, heads up. SG

Great news! We will plan for that week mid week then-

BTW on quick and dirty genetic test done a couple of years ago, the lab said the specimen was asian- no wonders asians and native americans are so short ;-). Just kidding...

Well maybe not!

At any rate we will plan on that week. Also, if Dr. Lachman's report can be finalized prior to then that would be helpful.

I appreciate the extensive and thorough work you are doing on this- Steve

Steve,

I've got everything ready. Some initial trials worked ok with test materials. The week of the 25th would work for me. Towards the middle is best. If I am to get any sequence back at all it will be then. My first amplifications will be against genomic regions that look for gene alleles that can geographically pinpoint gene frequencies for South American natives. This will immediately rule out that it is an indigenous "person". I will run two sets of amplifications on those (repeats), several "blank" controls (to control for contamination), and my own genome as well as "swabs" from the environment. The latter all control for the off chance someone has contaminated the premises with DNA of various types.

The room in which the materials are to be kept is under 24 hour constant video surveillance by Stanford security. The DNA should be extracted by this weekend from the bone, PCR can occur as soon as the oligos come in next week (3 day

turnaround from design to experiment ready), and if there is a PCR product it can be read by the end of the next week. These will be TARGETTED sequences that can not only tell me the racial makeup of the specimen, but also I will be reading certain "clock" genes that people use for dating of time since last common ancestor, if I can design the oligos in time I will target some of the mutations Dr. Lachman suggested.

If it's an indigene from South America the sequences will be negative only insofar as it's not 100% "different". If it's not an indigene... well we will see.

I hope work is going well...We are just back from an expedition to FL and wanted to touch base and see how the project is progressing.

The film team is suggesting coming up to see you at Stanford the week of Feb 25. Do you think that would work?

Very excited to hear of any results!

Best always,

Garry just so you know I will be arriving Tues evening Feb 26 at SFO- so if we need to meet on Feb 27 prior to filming on Feb 28 I will be in the Bay area.

I head to LA on Fri. March 1st at 7p.

Looking forward to seeing you soon. Steve

Steve,

Sounds good. I can make some time available the 27th for sure.

DNA is extracting tonight. I literally brought the sample home to do the incubation here because I don't trust the sample out of my sight—even with video surveillance.

I should have some estimates tomorrow afternoon on how much "primary" DNA was recovered. I will run the sample on a DNA size analyzer which will then determine which of two amplification protocols I should use. If the DNA is long—then it is best to do double stranded library preparation—for "well preserved" DNA. If the DNA is short, I will do the single stranded library preparation – for "ancient" DNA.

I have been chatting with [REDACTED] the guy who did the 70,000 year old Denisovan DNA (Asian Neanderthal relative)) and he has been quite helpful with protocols. I took a chance and I shared with him what I am "up to" and he seems quite open-minded. If there is something "real" here, he has offered for me to verify results in his lab at the Max Planck in Germany. Like me, he has published in Science and other top journals before, so he knows what it takes to prove something. Of course, I've found that scientists often get cold feet when the rubber meets the road, but at least the offer is there so far.

Steve,

Everything went well today. Sample is off for sequencing. Yee hah...

I will be submitting it to TWO other Centers tomorrow—I just could not get a hold of the tech reps today. I want to make sure I can get through to them in person and not send sample via mail. Call me paranoid, but I don't want the sample out of my sight for as much as I can let it, and I don't want an electronic trace of where it's been sent. Less chance of someone "interfering" with the data this way. Triple check on the sequence also is a cross-check for accuracy.
