USSR: New Beam Energy Possible?

By Lt. Col. T.E. Bearden, ^{US Army} USAF (Ret.)

The following paper, due to be presented at a USPA (United States Psychotronics Association) annual symposium in Georgia later this month, was written by T.E. Bearden, a nuclear engineer and a retired Lt. Col. in the US Air Force. The views expressed in the paper are entirely his own, and the Editor wishes to state that the paper is presented here entirely on its merit as an interesting discussion — and argument — about a widely noted phenomenon.

Shortly before the death of Leonid Brezhnev, the Soviet Union began "adjusting-in" a scalar interferometry grid across North America. The purpose of the grid, produced by interfering scalar beams from giant scalar wave transmitters in the USSR, was to directly influence the weather over the North American continent.

The adjustments left a signature: a series of micro-quakes in the earth and a series of anomalous "airquakes" across the country. The grid adjustment was apparently completed by February-March 1983.

With completion of the scalar grid, direct influence on North American weather began in earnest. Storm after storm hammered the California coast, then moved across the Rockies, dipped sharply down across Texas and Oklahoma, moved across Louisiana, Mississippi, and Alabama/Tennessee, and turned in to Georgia to move along the Adirondack chain, wrecking havoc all along the way. The giant jet streams dipped down in the center of the US with a classic bend that was repeated over and over again.

Then in the summer, drought conditions struck much of the US heartland. About half the nation's corn crop was lost, for example.

The winter of 1983-84 was particularly enlightening. Classic signatures appeared in the clouds at many places throughout the nation. Three major signatures were identified:

- 1.) A "cross-ploughed field" type pattern, where clouds formed straight lines, reaching from horizon to horizon east and west, and also from horizon

to horizon north and south. A spectacular example of this condition was seen over Huntsville, Alabama by the author and a personal friend.

- 2.) A "giant radial," where about two-thirds of a narrow-rimmed ring of cloud formed, about three to five miles in diameter. Outside the circle, long thin radial lines of clouds ran straight out, focused from the center of the ring. These thin, straight radials were 15-20 miles long, and one could directly see entire huge cloud systems captured and controlled by the giant radial. The giant radial strongly resembles the old Japanese "Rising Sun" symbol of World War II. Several spectacular examples of this formation were seen by the author and others in Florida, Southern Alabama, Northern Alabama, California and at 30,000 feet some 400 miles west of Memphis, Tennessee. Other persons observed giant radials at numerous locations over the US. An Iowa farmer reported that such a radial had occurred over his farm several times, each time severely disturbing all his chickens.

- 3.) A "twin giant radial" pattern, where two giant radials hook up at the arm extremities. In this case, the circular ring at the center disappears, and the radials are about three times as thick, with their inner ends boattailed. Two cases of such twin giant radials were again witnessed over Huntsville, Alabama.

During Christmas, cold records were broken in some 21 states and 60 cities. At least a dozen cities reported all-time low December temperatures. Over a hundred deaths were attributed to the frigid weather, and millions of dollars of citrus fruits and other crops were lost. Yet in Europe it was unseasonably warm, with December temperatures reaching as high as 70 degrees in Paris, for example. Storm activities across the US were unusual and included floods, extra heavy snow, extreme low temperatures and so forth.

El Niño is a famous warming disturbance in the waters of the Pacific Ocean. It usually occurs every decade and brings heavy rains to parts of South America. In April

1983 the *New York Times* reported that *El Niño* was much more extensive than usual. The entire eastern Pacific was affected, reaching from Alaska on the north to Chile on the south. This *El Niño* appeared much earlier than in any of its previous appearances. While it normally follows a period of unusually strong trade winds, in this appearance it did not. And normally it is much further out in the Pacific — this time it was displaced far to the east of its normal location.

The drastic change in *El Niño* displaced storms for hundreds of miles from their normal tracks, and barometric pressure over the Aleutians reached a low that occurs only "once in a century or so." *El Niño* itself, according to the *Washington Post*, was a hundred-year magnitude event, and it actually stalled the equatorial trade winds that normally blow from east to west. The stalling of the trade winds caused torrential rains in Peru, and severe drought in Australia. Great ocean currents of warm water were reversed from their normal movement toward Asia and backed up off the West Coast of South America. The giant jet streams over North America were shifted, and cold Arctic air spilled down, deep into the central and eastern US. A giant flip-flop of much of the world's weather occurred, with particularly severe results experienced in North America and Australia.

In early 1984 the floods began again, with spring flooding in Utah and Wyoming reaching record levels. Again, the remnant of a giant radial pattern was photographed over Huntsville, Alabama by the author. Anomalous airquakes over a large area of Tennessee and Alabama again occurred, possibly as a result of additional Soviet adjustments of the scalar grid.

In a one year period, the lowest pressure and highest pressure ever recorded both occurred — an unusual "coincidence," to say the least.

Only the fundamental concepts of scalar electromagnetic theory are presented here. Basic scalar mechanisms have existed in the literature for 25 years, and have been experimentally proven for 24 years. The mechanisms and effects occur even in the presence of zero electric and magnetic fields, and so do not occur in classical electromagnetics theory.

The Bohm-Aharonov (BA) Effect

These effects are lumped together in what is called the "Bohm-Aharonov Effect" in quantum physics. The first seminal paper was published by Aharonov and Bohm in 1959, and Chambers published the results of his experimental proof shortly thereafter in 1960. Since then some experiments have continued to be run and papers have continued to be written, but the effect is largely ignored by the vast mainstream of Western science.

The Bohm-Aharonov effects are absolutely required by quantum mechanics. But since they do not occur in ordinary EM theory, they are presently unknown to conventional Western scientists and engineers, who have ignored the zero-field effects. For example, it ap-

pears that a statement of the weapons implications of the BA effect did not even exist in the Western literature prior to papers written by this author. Obviously, with such a gap our intelligence analysts have not known of the effects and their implications. They also have not collated a picture of the Soviet scalar weapon developments, testing, and overt use against the US as hostile action.

It must be pointed out that an *artificial* potential can be produced by deliberately opposing electric or magnetic fields so that they vectorially sum to zero. The result becomes a "zero-vector field" insofar as resultant or "envelope" fields and external observers are concerned. This field has no electric or magnetic field, yet it possesses a multi-field substructure. It is a stress in spacetime vacuum itself. By varying the substructure vector components, with the resultants always summing to zero, a pure scalar potential wave — spatiotemporal stress wave — can be produced.

Each of the component electric and magnetic force fields in the zero summation are still *inclusively* present, though not *exclusively* present to an external observer. All the component energies are "infolded" against each other and locked-in as stress energy of vacuum, even though the wave possesses no "envelope" force field magnitude and hence no ordinary electromagnetic energy.

By interfering two beams of such scalar waves at a distance, a scalar interferometer is produced. Energy may be *produced* at the distant interference site, or it may be *extracted from* that distant site. No electromagnetic energy, as such, flows in the intervening space between the transmitters and the distant target site. This is Tesla's old "transmission of energy at a distance without losses," and scalar interferometry was his secret.

By adding energy at a distant interference site — say over North America — a high pressure area results at the target site. By extracting energy from the distant interference site, a low pressure area results at the target. By slow rotation of the transmitters, the entire distant interference zones — and the highs and lows — can be moved along. This allows the capturing and movement of huge cloud masses, direct manipulation of high and low pressure areas, diversion of jet streams, and extensive Soviet control over the weather patterns of North America.

Since scalar waves can travel through the ocean or through the earth with only limited attenuation, it is likely that Soviet transmitters were responsible for the highly anomalous location, appearance, and intensity of *El Niño* in 1982-1983. There is extensive evidence in the open literature of Soviet testing of scalar electromagnetic weapons on a global scale during the last two decades. Massive instances of sudden cooling of large areas have occurred as near-explosions of cold, up to 150 miles in diameter, at least 78 times ^{since} 1974. A recent example occurred off the coast of Japan, 200 miles from downtown Tokyo, on April 9, 1984. ■

reached the end of its rope. With the stakes mounting to potential megabucks in the next five years, the race is on to come up with a better, faster chip tester.....and BREAKTHROUGH believes we've spotted a likely winner. The winner's edge: Instead of inspecting small parts of each chip in a long series of operations (requires constant cross-referencing of data), the new breed of chip tester is able to look at very complex chips in one shot.....so much less time and money are spent on testing, and much more creative freedom is given to chip designers. The first machines are being delivered now. Cost: About \$2.5 million. BREAKTHROUGH expects to see installations in the top chip manufacturing companies by January 1985. The next step: Incorporating the tester into computer-aided design centers to speed customized chip manufacturing (see the special report in this issue). Out in front: MegaTest,* 1321 Ridder Park Dr., San Jose, CA 59131.

BUSINESS TECHNOLOGY Stiff Competition for Old-Style Floppies: New breed of floppy disk system stores as much as 40 times more data than today's standard, bringing computer users the power and convenience of hard disk systems without their tremendous cost. Imagine: New technology permits storage, on a single disk, of all the programs (word processing, spreadsheets, graphics, etc.) necessary for conducting business.....with enough room left over to accommodate a list of 25,000 names and addresses.....even enough blank space to accept hundreds of pages of notes. Bonus: The new system not only stores far more data, it also processes this information faster and with fewer mistakes. Paves the way for an onslaught of easier-to-use and more powerful software programs. Key: Newly developed techniques for recording and re-calling disk data. The first high-capacity floppy disk systems, available as add-on equipment within the next few weeks, will have a capacity of 3.3 megabytes (that's 10 times the capacity of today's average disk). Within 10 months capacity should rocket to 13.2 megabytes. Prediction: The new disk systems will be standard equipment on most personal computers and minicomputers by 1986. Cost: Disk drives about \$350; disks \$15 each. Disk developer: Spin Physics (subsidiary of Kodak), 11633 Sorrento Valley Rd., San Diego, CA 92121. Disk drive developer: Drivetec, Inc.,* 2140 Bering Dr., San Jose, CA 95131.

Self-Tuning Antennas: Shrink the size, cut the cost and increase the range and accuracy of cellular telephones, military telecommunications equipment, car radios, satellite dishes, high-fidelity receivers -- just about anything receiving or broadcasting radio and microwave signals. The situation: Over \$2 billion is spent on antennas every year.....but despite the huge market, antenna design remains crude (basically unchanged for decades) and amazingly inefficient. Only very large or very expensive electronic amplifiers and filters can pull in a strong, stable signal with today's antennas. Better way: New technology heightens sensitivity and compensates for changes in signal strength, background noise, etc. Key: A second conductor (the "pipe" that channels the signal) allows the antenna to vary its reception capability automatically. Result: A constantly balanced signal. And a super-antenna has 100 times the range of present models. So one antenna could handle several applications. Example: A single car aerial could pick up AM/FM, cellular and CB radios. No need to drill new holes and wire more aerials. And retrofitting is no problem -- the new antennas work great with existing equipment. Expected cost to consumer: \$10 to \$2,000, depending on the function. Licensing opportunity: Wes Olson, Snyder Antenna,* 250 E. 17 St., Costa Mesa, CA 92627.

New Springtime: Coiled steel springs are about to be declared dead. They have been used as shock absorbers in everything from automobiles to factory
