About 10% not matching. Higher than normal mismatch. Usually mismatch comes from errors in the sequencing or sample preparation and are a normal product of the noise generated in the experiment. The open question at the point is whether the "noise" is due to the "fragmented" DNA and condition of the specimen—independent of the biology of the specimen. Personally, the DNA fragmentation we saw in the original prep was far better than I expected, so I don't think it's that. But there always will be a critic who says "But you don't know". So I won't leave myself diplomatically open for attack there.

We just prepared another library from the original DNA and I am told the "quality is better" than the previous time. Now... quality does not mean we get more % matches necessarily... it more often means "More reads per unit of DNA input".

Part of the push right now is to get the ethnographic experts to help me cull the million of so mutations (most expected) for a signature or change that could be used to say the WHY of the morphology we see. Set aside ET/human—there has to be a mutation or change that explains the WHY of the morphology. Either that or one MUST invoke something strange that interfered to cause the mutation (remember thalidomide? No genetics... thalidomide, a teratogen, works by regulating epigenetic control points). Interestingly, a variant of thalidomide is used to kill certain cancers because the new therapeutic (made by Celgene) interferes with cancer's USE of epigenetics to evade chemotherapy.

DNA clock—as I said in a prior email to do that I need to get "control" DNA from aborted fetuses to create a standard clock. Review Board panels and approvals needed for that. I am starting that process but the paperwork ALONE will take me weeks to few months. More on carbon dating soon—there's a machine on campus we think we can adapt to the purpose that doesn't require milligrams of sample.

BTW how much DNA is not matching? JD told me 10%.

Also is there an estimate on how long ago he died? Anything more on the DNA clock or Carbon testing? Steve

By the way—the website I am thinking about will also make sure there's the open question of the unmatched DNA, etc. I am also thinking about how to appropriately add "epigenetics" and other issues previously discussed.

The mystery continues, including the notion there are more of these things supposedly—including the thing in Russia.

Excellent!

If you have time Thursday sometime please give me a call - We will do a press release next week early on the specimen and I'd like to get up to date on what you have found so far.

Thanks! Steve

Erin is one of the best graduate students I have had. He was co- first author on my lab's now well-known Science paper on mass Cytometry in 2011 (see attached).

Last couple of years I have been "indoctrinating" him into the area. At first he was annoyingly skeptical... as I kept showing him the evidence and letting him look at it he's come full circle.

He's a postdoc at UCSF now.

Nice.

The Atacama specimen looks a bit like "[REDACTED] of Kyshtym" discovered in 1996. Here is the most informative account on Alexis that I found, though the English is poor:

<http://survincity.com/2010/07/interesting-facts-the-alien-from-alexis-kyshtym/>

The video at the end is the highlight.

I wonder if you'll get the opportunity to do deep sequencing on "Alexis"... If this is due to a rare mutation, then having a 2nd sample might reveal it.

Someone found the history of it.

Best regards,

Garry
