Steve,

The spin and spin flipping phenomenon is of course well-known in physics and has been for a long time. It was just out of the mainstream of electrical engineering, etc. But they were known and investigated by materials science specialists. In the last decade or so these spin phenomena have received dramatically increasing attention, e.g., in the newly emerged technology of spintronics. Lots of gadgets these days are being made, using spins and spin flipping. It's a really up and coming new technology.

The momentarily very powerful exchange forces that also emerge from spin flips have been known for decades, but have just been a little obscure from the mainstream. E.g., the exchange force (e.g., mentioned in Feynman's three volumes) evoked in a permanent magnet assembly can be momentarily a thousand or more times stronger than the magnetic field forces there. So if one evokes a succession of such spin-flip-generated exchange forces in a rotary permanent magnet device, it is perfectly permitted to self-rotate with power, if there are enough of the exchange force firings and they are at the proper place, time, and in the proper direction. Then the integration of the linear force on the rotor does not integrate to zero around the closed rotation path, and that is known as a "nonconservative field" situation.

For the purely magnetic force resulting from attraction of unlike poles and repulsion of like poles, the force is conservative; i.e., if you integrate the propulsive effect of ($F \times \text{distance} \times \cos \text{angle}$), it integrates to zero NET force, around any closed path. If there are extra asymmetrical phenomena that occur in the closed path, however, this integration need not result in a net zero, and there can indeed be a net propulsion. That is called a "non conservative" field in that case.

Actually, nonconservative magnetic fields (such as in the case of multivalued potentials) arise naturally in the standard magnetic theory, but for many decades the exasperated theoreticians have considered this a big nuisance to be avoided at all costs! That's asymmetrical, and they are taught to love symmetry. When you integrate the magnetic force around a closed loop containing a multivalued potential, for example, the integration is not zero, and so again one has NET rotation drive and thrust, even from permanent magnet assemblies only, in both rotor and stator. In short, in real systems one really can get nonconservative forces, and it isn't that difficult for any modern lab. Yet the theorists have done everything humanly possible to "average out" or "argue away" and get rid of the hated multivalued magnetic potentials, thus reverting to conservative magnetic fields by sheer assumption and slight of hand, and deliberately discarding the nonconservative fields that are quite possible and that do occur in nature anyway. Anyone today considering just attraction and repulsion of unlike and like magnetic poles only, is decades behind materials science theory and discovery. Yet that is what the EEs consider and study, and that is what they are still taught to do in their actual build-ups and systems. We actually have a scientific mindset problem, not a scientific problem per

se.

CLOSE HOLD.  approach, e.g., for decades has been based on precise control of the spins and their flipping, to freely evoke those exchange forces in the rotation cycle where he wishes and when he wishes and in the direction he wishes. One of his favorite tricks to confound visiting Ph.D.'s used to be to show them a north pole attracting a north pole, then ask them to explain it. One gets some interesting responses on that one! One can find out instantly whether the fellow has any knowledge or consideration of exchange forces, or is just following naïve electrical power engineering.

For years Howard did not have the precision machining necessary to do the work to the proper tolerances, but had to painfully hand-cut the magnets with a diamond saw, which is just not sufficiently precise. It's about like trying to slice bread with a chain saw. So he just made build-up after build-up until he got one that worked by sheer random variation. The magnets for that one were promptly stolen by a mysterious break-in at his lab. Now he finally has the precision machining needed, has developed much better assemblies, and I strongly expect a Johnson rotary permanent magnet motor in the immediate future. I have a nonexclusive license for manufacture, production, and development of the motor when it is completed, and plan on heading up there this coming weekend to check on progress, document the progress, etc. When he gets it successfully working, I also plan to try to arrange with him to come to you with my license (nonexclusive) to develop, manufacture, and get it on the market if you are interested. The agreement would have to be a bit peculiar, because my license is non exclusive. It means that any improvement would have to be patented in Johnson's name, under a noncircumvention clause, and of course royalties would have to be paid to Johnson. He has other licensees as well, but almost all of them are thinking North pole/South pole. Anyway, if you are interested I will let you know on the progress as soon as I find out, etc. — all on close hold, of course. END OF CLOSE HOLD.

The other things the engineer was saying are also already developed or well along. The business of gathering in quantum mechanics and electrodynamics to produce a unified field theory is done, and one of the best examples is Sachs's theory. The advantage of Sachs's approach is that Evans and Vigier's $O(3)$ electrodynamics is a subset, and thus the $O(3)$ electrodynamics can be used to do unified field theory engineering. The disadvantage is that with such high nonlinearity, most things require numerical methods — but today that is not a problem, with the excellent training of young graduates and with computers and programs like Mathematica. In the old days numerical methods were anathema, but that is not true today. Indeed, Lorentz arbitrarily regauged the Maxwell-Heaviside equations primarily to escape having to use numerical methods nearly totally, and to be able to get closed solutions by algebraic analysis.

He is correct in visualizing that these areas are subject to direct EM engineering, when one has a higher group symmetry electrodynamics. I like to express it as the "supersystem", where one has three components: (1) the normal physical system and its interactions, (2) the local active vacuum and its interactions, and (3) the local curvatures of spacetime and their dynamics. All three components of the supersystem actually interact with each other. Classical Maxwell-Heaviside theory assumes that the other two parts of the supersystem are void; in short, that the local spacetime is always flat (in theory one can't even have an EM wave in space with that

assumption!) and the local vacuum is inert. So the standard EE is out of it, forever, as far as overunity systems are concerned. It does not allow an active environment that could be furnishing extra energy. You have to go to quantum theory to even explain the common solar cell, which produces COP = infinity even though its efficiency may be only 17%, in which case it wastes 83% of all the energy the environment freely inputs to it.

All that split between the various disciplines changes when one utilizes a higher group symmetry electrodynamics. Unfortunately, most of the scientific community continues to insist on using a hoary old classical EM that destroys the very supersystem needed for COP>1.0 and self-powering. That way, the gas meter stays on the gas pump and the power meter stays on the house. And we continue to be dependent on foreign oil, and there's an escalating energy crisis, and the biospheric destruction continues. But certain very powerful folks continue to rake in enormous profits annually, worldwide.

The eerie thing is that the same tired old Maxwell-Heaviside theory implicitly assumes that every EM field and EM potential, and every joule of EM energy in the universe, is and has been freely created from nothing at all by the associated source charge(s)! In all human history, there have never been so great a number of profound though unwitting advocates of forbidden perpetual working machines, as the conventional scientific establishment in continuing to maintain and teach a model with such an astounding assumption. To borrow a phrase from Tesla, it's an inexplicable aberration of the scientific mind.

Best wishes,

Subject: Fwd: Quantum Standing Waves

What do you think of these concepts. Have you heard of this gentleman? Best always, Steven
