

From CTG – March 30 2018

XXXX says that the Chilean mummy has lots of “random chance” mutations, which affected 7 different genes for “bone development” all at once.

2 If such mutations were really “random” as he says, then practically every other gene of similar DNA length would also be mutated, meaning at least one-quarter to one-half of the 30,000 genes in a human genome!

Quite obviously, if this were the case, then the fertilized embryo would not have been able to divide even once. Even an inherited single-gene disorder (1 gene mutated out of 30,000) can cause serious developmental problems.

THE END
