Dear Dr. Greer (Steve),

Wednesday night your time (Thursday noon here) would be good for me. We are currently **UTC plus 11 hours AEDT**. I promised to play golf with two friends later in the afternoon. I can send you a Friend Request on Skype if you provide details? My username is "**collie2**" at this email.

If you look at the paper I sent earlier, you can see in Figure 1 (page 738) that the total sequence heterogeneity of bone DNA kept in a museum for 90 years is 0.3% to 0.5%, or 1 mutation per 200 to 300 bp. That would give 3 to 5 mutations per 1000 bp coding region, consistent with what Nolan and colleagues report. Other studies try to get nuclear DNA from old mummies, but unreliably and with great difficulty. Studies of pregnant women show that taking nitroso drugs can produce birth defects in the first trimester, but not sodium nitrate as found in food.

[REDACTED] seems to have taken all of the sequences from that mummy, and selected in a first step just the ones which match "human" (89%). He does not say much about the other 11%. Then he says that his selected human sequences match a Chilean person. Except many genes are highly mutated! Well, it was an old and somewhat damaged sample. I would be grateful to learn of any other plausible theories?

Best wishes, [REDACTED] in sunny Sydney
