Steve,

Good. Glad we are of a mind on this. I never want to "disappoint" when I set out on a project.

Yes—never thought of that: That it had to die of a traumatic event rather than due to its pathology, is a puzzle. I am beginning to believe in Arthur C. Clarke's "magic" and technology the more and more I delve into this.

I still have two more readings of the genes to come (full genomes). So this little guy will soon enough have about 60-100X coverage. His DNA (fair to call him a "he" now) is getting more attention than most people.

More later.

Thanks 

To be honest, I never expected the genome to be greatly different from humans... Although I do not usually speak of this publicly, I take seriously the traditions of countless native people that contend that we (humans) have descended and are literally connected to visitors from the stars...Of course the anthropological, religious, ethnographic and biological ramifications of such thoughts are mind-boggling, and would be disturbing to most modern scientists (and theologians!)- but not to most native peoples, I have found.

At any rate, the phenotype and the genotype do not add up-- and  and Lachman view of a creature that was up walking around for a least a few years is hard to square with a mere unknown genetic mutation resulting in some type of human dwarfism. Clinically, I do not

see how a 6 inch creature could have lived to that age, even today, never mind a few decades or centuries ago.

So the enigma continues- as I thought it would- and I am not at all disappointed, but more intrigued as to the true meaning of these findings in the aggregate. If the genetics hold up in the months (or years?!) ahead, what was this creature, and how did it survive? And given that it appears to have died of a peri-mortum traumatic event, and not an intrinsic medical condition per se, the question becomes from whence did it come? And why was it here? And how did it live and survive in such a primitive area being so diminutive? I am sure that we would be hard-pressed to find a neonatologist on earth today that could keep so tiny a baby alive today, never mind many years ago...And never mind one so "deformed", if indeed "human" (whatever human means at this point!)

Now we really must get to the Atacama!

Steve,

Working with the people at my company tomorrow to gather more information.

First pass. Human. As before, mitochondria shows an allele frequency consistent with indigenous peoples of the Chilean Andes—meaning the mother was “human native” to the region. Checked all the “known” places in the genome for things like primordial dwarfism and other skeletal dysplasia genes that would be “consistent” with some of the bone abnormalities (PCNT, FGFR2,3, and ribosomal helper RNAs). Nothing there so far found. Round up the usual suspects can be dismissed—confirming [REDACTED] analyses.

All the mutations so far are consistent with what is found in the allele variant databases. Meaning; Most of the “mutations” first called out by the program are actually KNOWN variants normally found ACROSS human racial groups. I had to go back and find the right databases to crosscheck. This is especially important because I am NOT picking up any considerable “ancient DNA” signature... meaning at a minimum the DNA is on the order of decades to low hundreds of years old. So the mutations I am finding are “real”, but I cannot readily assign an obvious function. I am finding VERY FEW mutations that are NOT in the allele variant databases. Meaning: If I were given this sequence “blind” I would assume it’s a native human from this era.

First pass. Human. As before, mitochondria shows an allele frequency consistent with indigenous peoples of the Chilean Andes—meaning the mother was “human native” to the region. Checked all the “known” places in the genome for things like primordial dwarfism and other skeletal dysplasia genes that would be “consistent” with some of the bone abnormalities (PCNT, FGFR2,3, and ribosomal helper RNAs). Nothing there so far found. Round up the usual suspects can be dismissed—confirming Dr. Lachman’s analyses.

All the mutations so far are consistent with what is found in the allele variant databases. Meaning; Most of the “mutations” first called out by the program are actually KNOWN variants normally found ACROSS human racial groups. I had to go back and find the right databases to crosscheck. This is especially important because I am NOT picking up any considerable “ancient DNA” signature... meaning at a minimum the DNA is on the order of decades to low hundreds of years old. So the mutations I am finding are “real”, but I cannot readily assign an obvious function. I am finding VERY FEW mutations that are NOT in the allele variant databases. Meaning: If I were given this sequence “blind” I would assume it’s a native human from this era.

Tomorrow morning I will be diving into the “outlier” mutations to see if there is anything there that explains the defects. Then, I have to start on the more difficult task of looking at the “refuse” un-aligned sequences. Millions of sequences did not “align” and the “super specialists” who do this every day say the amount of non-mismatch is unusual. So there could be an answer there, but it will take a whole new computational approach to “align contigs”.

I’ve a long way to go, but this is an extreme puzzle... first it’s not obviously “non-human” in the DNA I have sequenced (I got as much as a 17-fold over-coverage of the sequence). As I said before, 30-fold is considered “full coverage”.

So the reason for the deformities are not obvious at the protein level. Now, there is the whole “non-coding” genome issue. Thousands of unmapped expressed DNA regions (so-called non-coding expressed genome) that could be at the bottom of this to explain the defects. But that is COMPLETELY uncharted waters and proving any changes I find there will be difficult. In a couple of weeks I am getting together with a Nobel Prize winner at Stanford who won the prize for certain non-coding RNAs and he might have some hints, but there will be no solution from him, just places to keep looking.

Now, if we want to believe there are more of these things as you stated, and we assume they are ET, then something else is going on. As before, let me speculate—wildly—let’s say an advanced ET civilization has a need or desire to “instantiate” itself locally. Imagine a wholly non material intelligence, machine intelligence, or an intelligence that feels a need to create “workers” out of local “materials”. You could imagine they could use any of a variety of techniques to “print” living things using the local sentient fauna as raw materials. Or, they could use other advanced techniques to epigenetically or otherwise “force” development in ways that give rise to what we see as this specimen. Again—wild speculation, but I am stumped by the lack of clues so far in the genome.

Given what we know about the technologies ETs are using for their ships—an obvious control over matter at the subatomic level with master level understanding of how to manipulate the quantum states of materials-- and likely an ability to “print” ships like our 3D printers you’ve likely heard about—and you could imagine about anything.

Absent some “aha” moment tomorrow morning, the above will be what I will relay in the final filming. Sorry nothing obvious is jumping out, but the data is the data. Of course, I as much as you wanted a smoking gun (darn, there goes my Nobel Prize).

But, now that we have done this I hope we can coax others who might have other specimens like this one (or even some of the other bodies) to come forward. The turn-around time should be

much faster since I've got the pipeline created. Hopefully you can use your platform to make a call for such specimens.

Best regards,
