Subject: First half or so of the package

[REDACTED] and Steve,

Attached is the first half of the 10 Mbytes or so of pdf files.

The original patent application was Appl. N. 09/656,313, filed Sep. 6, 2000. Later after some objections by the patent office, and our group's rebuttal, our patent #6,362,718 B1 was issued (from that application) on Mar. 26, 2002.

Application #10/081,847 filed on (TBD) was actually a continuation filed on that same original patent application 09/656,313, as per Norm Freedland's letter of Feb. 15, 2002. This continuation, of course, was filed before the present patent #6,362,718 B1 was issued.

This explains why all the up front language in the continuation, down to the section on claims, is exactly the same as in our issued patent. It was simply matched to the basic application 09/656,313 at the time. So what the continuation filing was supposed to do was simply add additional claims.

Now comes the patent office action on this continuation. Ugh! Since the continuation also contains the body of our issued patent, the objections as to perpetual motion, violating first and second law of thermodynamics, etc. is thus also a flat rejection of our patent, WITHOUT OVERTLY SAYING SO YET. You can see the trap. This is probably a clever move by the Patent Office to negate the patent (after probably many quiet contacts from the skeptics and the slander and libel community). Methinks yon Cassius hath a lean and hungry look!

We will be addressing the issues raised by the Patent office, and other than lengthy they are not too big a problem. I can mostly extract and modify things I've already written, with some effort of course.

The kicker in the thing is that, to my understanding, our attorney was supposed to file a continuation with all the Aharonov-Bohm stuff in it etc., prior to Christmas. I'm still trying to find out if that was filed, and get a copy of what was filed, if it was. So that part is unclear yet.

Anyway, now we have to fight the battle against equilibrium thermodynamics (the MEG uses nonequilibrium thermodynamics), the limitations of the classical EE model, etc.

2/22/04

As you can see, the patent examiner also did not even know the difference between efficiency of a system and coefficient of performance. He reiterated the tired old saw that $COP > 1.0$ violates the first law of thermodynamics (conservation of energy!). Actually that is stupid; the common solar cell power array may have an EFFICIENCY of only 17%, and waste 83% of all the solar energy that is input, but it still has a $COP = \text{infinity}$! As does a windmill with an efficiency of about 50%. Or a sailboat. Or a waterwheel. Or a hydroelectric system can be, when one counts the river's input. The river inputs it all and the operator inputs nothing. So the total useful electrical output divided by the OPERATOR'S zero input gives a $COP = \text{infinity}$.

Best wishes,
